At 02:36 we have welding of the WTC perimeter columns. You need approx 2-3 full time welders on each tower do do this, so it is not very expensive. The concrete floors are at 11:50. Casting on-site also produce flat floors with no bending, that actually occurs on the steel underneath. Note that the steel lattice get cast together by the concrete.
This was included in material given to Tom Alandh at SVT in September 2008.

The thickness of the steel belt, that run around each floor in the Towers, has been measured approximately, from this video, to be between 35 and 68mm. As an assumption, one-inch (25.4mm)x1.32m (52") can be used for calculations.
